Problem 8.

$\Leftarrow$  Let graph  $G$  have 1 vertex and 0 edges. By definition graph  $G$  is acyclic.

Notice that any connected graph has  $t$  vertices and  $t - 1$  edges, where  $t \in \mathbb{Z}$ . Accordingly the sum of all vertex degrees in  $G = 2(E(G)) = 2(V(G)) - 2$ . Therefore there exists a vertex with a degree  $\geq 2$ . Similarly a vertex's degree can't  $= 0$  or else the graph would be disconnected, so the degree  $= 1$ . Consider the graph  $G - v$ .  $G - v$  has  $V(G) - 1$  vertices and  $E(G) - 1 = V(G) - 2$  edges. By the induction hypothesis it is acyclic. Adding  $v$  to  $G - v$  can't create a cycle because the cycle would traverse  $v$ 's edge twice. Therefore  $G$  is acyclic.

$\Rightarrow$  Let graph  $G$  have 1 vertex, this means there is at most 0 edges. By definition graph  $G$  is acyclic.

Consider an acyclic connected graph with more than 1 vertices. If we choose a random vertex  $v_0$  and follow a path  $(v_1, v_2, \dots)$  by picking a vertex  $v_{i+1}$  that is adjacent to vertex  $v_i$  and is not already in the path. This path will end at some vertex  $v_k$ . If  $v_k$  is adjacent to some vertex  $v_t$  where  $v_t \neq v_{k-1}$  then a cycle has been discovered. Also, if  $v_k$  has an adjacent vertex that isn't in the path, then the path wouldn't have ended at  $v_k$  it would have ended at  $v_{k+1}$ . So  $v_k$  is adjacent to only  $v_{k-1}$  and therefore has a degree of 1. By removing  $v_k$  to form  $G - v_k$  which is an acyclic graph with  $V(G) - 1$  vertices and  $E(G) - 1$  edges. By the induction hypothesis we have  $E(G) - 1 = V(G) - 2$  which means the connected acyclic graph  $G$  has edges  $= V(G) - 1$ .

Problem 10.

$\Leftarrow$  Let  $T$  be a tree. By definition it is connected (any 2 vertices are joined by at least one path)

If any 2 vertices,  $u$  and  $q$  of  $T$  are joined by 2 or more paths then a cycle is produced.

This creates a contradiction with the definition of a tree.

$\Rightarrow$  Let  $T$  be a graph where any 2 vertices are connected by a unique path.

Thus  $T$  is connected. However, for any 2 vertices, if a cycle contains  $u$  and  $q$  then  $u, q$  are connected by more than 1 path. This produces a contradiction.

Problem 15.

If a graph  $G$  has  $n$  vertices and  $n - 1$  edges it does not have to be a tree. For a Graph to be a tree it must be connected and acyclic. If graph  $G$  has  $n - 1$  edges while also being connected, it is impossible for  $G$  to be cyclic. However, simply being acyclic does not make Graph  $G$  a tree. Graph  $G$  still must be connected and since the question only defines graph  $G$  as having  $n$  vertices and  $n - 1$  edges we cannot make any assumptions of  $G$  being connected. The image below shows a graph that has 5 vertices and 4 edges. This graph is disconnected and cyclic therefore it is not a tree and proves that a graph having  $n$  vertices and  $n - 1$  edges does not make that graph a tree.

notTree.png

Problem 24.

Assume we have a nontrivial tree  $G$ . By definition of a tree, every vertex  $v$  in  $G$  has one unique path to every other vertex  $q$  in  $G$ . By deleting any edge in the path  $(v, q)$ , vertex  $v$  and every vertex it still has a path to is no longer connected to vertex  $q$  and every vertex it still has a path to. Therefore there are now exactly 2 separate components after the deletion of any edge in graph  $G$ .
